

Regarding the dependencies for the app.py file, some of the ones we're familiar with are the flask templating, flask, and psycpg2. Starting with the data gathered from the database table, we know that we had to import sql from psycpg2 so that we could use sql.Identifier and sql.Literal to make the SQL statements more robust. We can see this graphically depicted where psycpg2.sql is down stream of psycpg2. Additionally, we can see where flask joins with the statements gathered from psycpg2 to substitute the variables storing the data into the respective template placeholders. Further, we see

flask.templating which is responsible for rendering of our template folder storing the templates for the webpage.
